Question 1: 27 marks

The Duffing equation $\ddot{x} - c\dot{x} - 4x + x^3 = 0$, with damping constant c , models the motion of a mechanical system in a twin-well potential field.

- (a) Rewrite this second order ODE as a system of first order ODEs.
- (b) For $c = 0$
 - (i) Find all critical points of the system.
 - (ii) Use linearisation to classify the nature and stability of the critical points
 - (iii) Use the chain rule to solve for the phase curves $y_2 = y_2(y_1)$.
 - (iv) Does the linearised system exhibit qualitatively similar behaviour as the nonlinear?
- (c) (Mathematica) Verify results from part (b)(ii), (iii), and (iv) by plotting a vector field.
- (d) For $c = 2$
 - (i) Find all critical points of the system.
 - (ii) Calculate the linearised system about each critical point. Classify their nature and stability. If a critical point is a saddle or a node, identify the relevant eigenvalues and eigenvector. If a critical point is a spiral or a centre, describe the direction of rotation, vertical nullclines, and direction field along the axes.
 - (iii) Does the linearised system exhibit qualitatively similar behaviour to the nonlinear?
 - (iv) Sketch a phase portrait for the non-linear system, by hand. Clearly identify each of the critical points and determine the heteroclinic orbit.

Solution: (a)

$$\text{Let } y_1 = x, \quad y_2 = \dot{x}.$$

$$\text{Then } \dot{y}_1 = y_2, \quad \dot{y}_2 = cy_2 + 4y_1 - y_1^3$$

Therefore, the second order ODE, as a system of first order ODEs is given by

$$\begin{cases} \dot{y}_1 = y_2 \\ \dot{y}_2 = cy_2 + 4y_1 - y_1^3 \end{cases}$$

Solution: (b)(i)

Letting $c = 0$, we have

$$\begin{cases} \dot{y}_1 = y_2 \\ \dot{y}_2 = 4y_1 - y_1^3 \end{cases}$$

Critical points satisfy $\dot{y}_1 = \dot{y}_2 = 0$.

If $\dot{y}_1 = 0$ then $y_2 = 0$.

If $\dot{y}_2 = 0$ then $0 = 4y_1 - y_1^3 = y_1(4 - y_1^2)$. This means $y_1 \in \{0, -2, 2\}$.

Therefore, we have critical points at:

$$(0, 0), \quad (-2, 0), \quad (2, 0)$$

Solution: (b)(ii)

We find the Jacobian of the system,

$$J(y_1, y_2) = \begin{pmatrix} \frac{\partial \dot{y}_1}{\partial y_1} & \frac{\partial \dot{y}_1}{\partial y_2} \\ \frac{\partial \dot{y}_2}{\partial y_1} & \frac{\partial \dot{y}_2}{\partial y_2} \end{pmatrix} = \begin{pmatrix} \frac{\partial}{\partial y_1} y_2 & \frac{\partial}{\partial y_2} y_2 \\ \frac{\partial}{\partial y_1} (4y_1 - y_1^3) & \frac{\partial}{\partial y_2} (4y_1 - y_1^3) \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 4 - 3y_1^2 & 0 \end{pmatrix}$$

Now, we can substitute our 3 critical points:

$$J(0,0) = \begin{pmatrix} 0 & 1 \\ 4 & 0 \end{pmatrix}, \quad \lambda^2 - 4 = 0 \implies \lambda = \pm 2.$$

Real eigenvalues with opposite sign \implies the critical point is an unstable saddle point, along eigenvectors $(1, 2)^T$ for $\lambda = 2$ and $(1, -2)^T$ for $\lambda = -2$.

$$J(2,0) = \begin{pmatrix} 0 & 1 \\ -8 & 0 \end{pmatrix}, \quad \lambda^2 + 8 = 0 \implies \lambda = \pm 2\sqrt{2}i$$

Complex eigenvalues \implies stable centre of the linearised system. Rotation is clockwise.

$$J(-2,0) = \begin{pmatrix} 0 & 1 \\ -8 & 0 \end{pmatrix}, \quad \lambda^2 + 8 = 0 \implies \lambda = \pm 2\sqrt{2}i$$

Exact same nature and stability as previous.

Solution: (b)(iii)

For the phase curve $y_2 = y_2(y_1)$, we note

$$\frac{dy_2}{dy_1} = \frac{\dot{y}_2}{\dot{y}_1} = \frac{4y_1 - y_1^3}{y_2}.$$

We can collect terms,

$$\frac{dy_2}{dy_1} = \frac{4y_1 - y_1^3}{y_2} \iff y_2 dy_2 = (4y_1 - y_1^3) dy_1.$$

Let's now integrate both sides:

$$\int y_2 dy_2 = \int (4y_1 - y_1^3) dy_1 \iff \frac{1}{2}y_2^2 = 2y_1^2 - \frac{1}{4}y_1^4 + C_1.$$

That is to say,

$$y_2^2 = 4y_1^2 - \frac{1}{2}y_1^4 + C$$

Solution: (b)(iv)

The linearised phase plane is qualitatively similar to the nonlinear system near each critical points: a saddle at the origin and centers at $(2, 0)$ and $(-2, 0)$. However we must be cautious because linearisation is a local tool and the global features (like how trajectories join up across wells) is not determined by the linear model alone.

Solution: (c)

Figure 1: HAND DRAWN (*in paint). Note the critical points in red, the nullclines in light blue, and the stability/directionality of the spirals highlighted in darkerblue.

Solution: (d)(i)

Letting $c = 2$, we have

$$\begin{cases} \dot{y}_1 = y_2 \\ \dot{y}_2 = 2y_2 + 4y_1 - y_1^3 \end{cases}$$

Critical points satisfy $\dot{y}_1 = \dot{y}_2 = 0$.

If $\dot{y}_1 = 0$ then $y_2 = 0$.

If $\dot{y}_2 = 0$ then $0 = 2y_2 + 4y_1 - y_1^3 = (4 - y_1^2)y_1 + 2y_2$, but since $y_2 = \dot{y}_1 = 0$ at a critical point, we can simplify this to $0 = (4 - y_1^2)y_1 \implies y_1 \in 0, -2, 2$.

Therefore, we get the same critical points as when $c = 0$, namely,

$$(0, 0), \quad (-2, 0), \quad (2, 0)$$

Solution: (d)(ii)

The Jacobian for $c = 2$ is similar as that for $c = 0$:

$$J(y_1, y_2) = \begin{pmatrix} \frac{\partial \dot{y}_1}{\partial y_1} & \frac{\partial \dot{y}_1}{\partial y_2} \\ \frac{\partial \dot{y}_2}{\partial y_1} & \frac{\partial \dot{y}_2}{\partial y_2} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 4 - 3y_1^2 & 2 \end{pmatrix}.$$

Now, we can substitute our 3 critical points:

$$J(0, 0) = \begin{pmatrix} 0 & 1 \\ 4 & 2 \end{pmatrix} \implies \lambda = 1 \pm \sqrt{5}.$$

One eigenvalue is less than zero $\lambda_1 = 1 - \sqrt{5}$, and the other, $\lambda_2 = 1 + \sqrt{5}$ is greater than 0. Hence, we have an unstable saddle. The unstable eigenvector is $(1, 1 + \sqrt{5})^T$, while the stable eigenvector is $(1, 1 - \sqrt{5})$.

$$J(-2, 0) = \begin{pmatrix} 0 & 1 \\ -8 & 2 \end{pmatrix} \implies \lambda = 1 \pm \sqrt{7}i$$

Because we have $\Re \lambda = 1 > 0$, we have unstable spirals, spinning clockwise. Further, we have $y_1' = 0 \iff y_2 = 0$, hence the gradient on the y_1 -axis is vertical: a vertical nullclines.

$$J(2, 0) = \begin{pmatrix} 0 & 1 \\ -8 & 2 \end{pmatrix} \implies \lambda = 1 \pm \sqrt{7}i$$

So the analysis is exactly the same as the previous.

Solution: (d)(iii)

Since all three equilibria are hyperbolic ($\det J(y_1, y_2) \neq 0$), the linearised system is equivalent to the nonlinear system, in some neighbourhood around each critical point. Therefore, the types and stability at these critical points between either system are the same.

Question 2: 6 marks

Consider the non-linear system of ODEs

$$\begin{aligned}y_1' &= f_1'(y_1, y_2) = -2y_1(3 - y_2 - y_1) \\ y_2' &= f_2'(y_1, y_2) = y_2(-4 + y_1 + 2y_2)\end{aligned}$$

- (Mathematica) Find all critical points of the system.
- (Mathematica) Calculate the linearised system about each critical point. Classify their type and stability.
- (Mathematica) Find the nullclines of the system.
- (Mathematica) Sketch a phase portrait for the non-linear system. Clearly identify each critical point and nullcline.

Solution: (a)

```
1 In[1] := f1[y1_, y2_] := -2 y1 (3 - y2 - y1);
2 In[2] := f2[y1_, y2_] := y2 (-4 + y1 + 2 y2);
3
4 In[3] := critRules = Solve[{f1[y1, y2] == 0, f2[y1, y2] == 0}, {y1, y2}];
5 In[4] := critPts = ({y1, y2} /. critRules)
6
7 Out[4]= {{0,0},{0,2},{2,1},{3,0}}
```

Solution: (b)

```
1 In[1] := J = D[{f1[y1, y2], f2[y1, y2]}, {{y1, y2}}]
2 Out[1]:= {{2 y1-2 (3-y1-y2),2 y1},{y2,-4+y1+4 y2}}
3 In[2] := Do[
4     Module[{pt, A, eigs},
5         pt = critPts[[k]];
6         A = J /. Thread[{y1, y2} -> pt];
7         eigs = Eigenvalues[A];
8         Print[pt, " -> Eigenvalues: ", eigs];
9         ],{k, Length[critPts]}
10 ]
11 [OUTPUT:]
12 {0,2} -> Eigenvalues: {4,-2}
13 {2,1} -> Eigenvalues: {3+Sqrt[5],3-Sqrt[5]}
14 {3,0} -> Eigenvalues: {6,-1}
15 {0,0} -> Eigenvalues: {-6,-4}
```

Therefore, the critical point at

- (0,0) is a stable node (2 real negative eigenvalues)
- (0,2) is an unstable saddle (2 real, opposite sign eigenvalues)
- (2,1) is an unstable saddle (2 real, opposite sign eigenvalues)
- (3,0) is an unstable node (2 real positive eigenvalues)

Solution: (c)

```
1 In[1] := nullcline1 = Reduce[f1[y1, y2] == 0, {y1, y2}]
2 In[2] := nullcline2 = Reduce[f2[y1, y2] == 0, {y1, y2}]
3 In[3] := {nullcline1, nullcline2}
4 Out[3]:= y1==0|y2==3-y1
5 Out[4]:= y2==0|y2==2-y1/2
```

Solution: (d)

```
1 In[1] := phasePortrait = StreamPlot[
2     {f1[y1, y2], f2[y1, y2]},
3     {y1, Sequence @@ {-1, 6}}, {y2, Sequence @@ {-1, 4}},
4     StreamStyle -> Directive[GrayLevel[0.35], Arrowheads[0.02]],
5     StreamPoints -> Fine,
6     PlotRange -> All,
7     FrameLabel -> (Style[#, 14] & /@ {"y1", "y2"}),
8     ImageSize -> 520
9 ];
10
11 In[2] := nullcline1 = ContourPlot[
12     f1[y1, y2] == 0,
13     {y1, Sequence @@ {-1, 6}}, {y2, Sequence @@ {-1, 4}},
14     ContourStyle -> {Thick, Red},
15     PlotLegends -> Placed[{Style["f1=0", Red]}, {0.85, 0.15}],
16     PlotRange -> All
17 ];
18
19 In[3] := nullcline2 = ContourPlot[
20     f2[y1, y2] == 0,
21     {y1, Sequence @@ {-1, 6}}, {y2, Sequence @@ {-1, 4}},
22     ContourStyle -> {Thick, Blue},
23     PlotLegends -> Placed[{Style["f2=0", Blue]}, {0.85, 0.08}],
24     PlotRange -> All
25 ];
26
27 In[4] := critPtsGraphic = Graphics[{
28     {Black, PointSize[0.02], Point[critPts]},
29     Table[
30         Inset[
31             Style[ToString[pt], 12, Black, Background -> White],
32             pt, {Left, Bottom}, {Automatic, Automatic}
33         ],
34         {pt, critPts}
35     ]
36 }];
37 In[5] := Show[phasePortrait, nullcline1, nullcline2, critPtsGraphic, PlotRange -> All]
38 Out[5] :=
```

Figure 2: Final phase space plot for Question 2(d). Note clearly labeled critical points in black, the nullclines in red, and the lines of 0 or ∞ gradient in blue.

Question 3: 7 marks

(a) (Mathematica) Solve the first order DE

$$\frac{dy}{dt} + \frac{2}{t}y(t) = \frac{1}{t^2}$$

(b) Consider the IVP

$$ty'' + 2ty' - 2y = -2, \quad y(0) = 1, \quad y'(0) = 2.$$

(i) Apply the Laplace transform to solve for $Y(s)$.

(ii) Apply the inverse Laplace transform to $Y(s)$, yielding the solution $y(t)$.

Solution: (a)

```
1 In[1] := DSolve[a'[t] + (2/t) a[t] == 1/t^2, a[t], t]
2 Out[1] := {{a[t] -> 1/t + C[1]/t^2}}
```

Hence,

$$y(t) = \frac{1}{t} + \frac{c}{t^2}$$

Solution: (b)(i)

We'll apply the Laplace transform, then solve for $\mathcal{L}\{y(t)\}(s) =: Y(s)$

$$\mathcal{L}\{ty'' + 2ty' - 2y\}(s) = \mathcal{L}\{-2\}(s)$$

First we'll apply linearity,

$$\mathcal{L}\{ty''\}(s) + 2\mathcal{L}\{ty'\}(s) - 2\mathcal{L}\{y\}(s) = -2\mathcal{L}\{1\}(s)$$

From the table we have the identities

$$\begin{aligned} \mathcal{L}\{tf(t)\} &= -\frac{d}{ds}\mathcal{L}\{f(t)\}(s) = -\frac{dF}{ds} =: -F'(s) \\ \mathcal{L}\{f^{(n)}(t)\}(s) &= s^n F(s) - \sum_{i=0}^{n-1} s^i f^{(n-i)}(0) \end{aligned}$$

From left to right...

$$\begin{aligned} \mathcal{L}\{ty''\}(s) &= -\frac{dy}{ds}(s^2Y(s) - sy(0) - y'(0)) \\ &= -\frac{dy}{ds}(s^2Y(s) - s - 2) \\ &= -2sY(s) - s^2Y'(s) + 1 + 0 \\ &= -2sY(s) - s^2Y'(s) + 1 \\ \mathcal{L}\{ty'\}(s) &= -\frac{dy}{ds}(sY(s) + y(0)) \\ &= -\frac{dy}{ds}(sY(s) + 1) \\ &= -Y(s) - sY'(s) \\ \mathcal{L}\{y\}(s) &= Y \\ \mathcal{L}\{1\}(s) &= \frac{1}{s} \end{aligned}$$

After substituting these values and doing some simplifying, we find that

$$Y'(s^2 + 2s) + Y(2s + 4) = 1 + \frac{2}{s}.$$

Let's now divide through by $s(s+2)$

$$\begin{aligned}Y' + Y \frac{2s+4}{s(s+2)} &= \frac{1}{s(s+2)} + \frac{2}{s^2(s+2)} \\Y' + Y \frac{2}{s} &= \frac{s+2}{s^2(s+2)} \\Y' + \frac{2}{s}Y &= \frac{1}{s^2}\end{aligned}$$

We note that this is the exact same DE as was given (and solved) in the previous question! This allows us to conclude that

$$Y(s) = \frac{1}{s} + \frac{C}{s^2}$$

Solution: (b)(ii)

Now we'll apply the inverse Laplace transform to $Y(s)$, hoping to yield the solution, $y(t)$.

$$\mathcal{L}\{Y(s)\}^{-1}(t) = \mathcal{L}\left\{\frac{1}{s} + \frac{C}{s^2}\right\}^{-1}(t)$$

We'll start by applying linearity

$$\mathcal{L}\{Y(s)\}^{-1}(t) = \mathcal{L}\left\{\frac{1}{s}\right\}^{-1}(t) + C\mathcal{L}\left\{\frac{1}{s^2}\right\}^{-1}(t)$$

From the table we have

$$\mathcal{L}\{1\}(s) = \frac{1}{s} \quad \text{and} \quad \mathcal{L}\{t\}(s) = \frac{1}{s^2}$$

Applying them, we get

$$\mathcal{L}\{Y(s)\}^{-1}(t) = 1 + Ct = y(t)$$

Applying the initial condition now,

$$\begin{aligned}y'(t) &= \frac{d}{dt}(1 + Ct) \\&= C \\y'(0) &= 2 \iff C = 2 \\ \therefore y(t) &= 1 + 2t.\end{aligned}$$

Question 4: 10 marks

- (a) Find the Laplace transform of $f(t) = t^5 e^{-4t} - 7 \sin(6t)$.
 (b) Let $f(t)$ satisfy the following identity

$$f(t) = (t-1)^2 u(t-1) + \int_0^t f(\tau) \sin(t-\tau) d\tau.$$

Find the Laplace transform of $f(t)$.

- (c) (Mathematica) Use the Laplace-transforms method to solve the IVP

$$\begin{cases} y_1'(t) = 3y_1(t) - 4y_2(t), \\ y_2'(t) = 3y_2(t) - 4y_1(t) \end{cases}$$

with initial conditions, $y_1(0) = 0$ and $y_2(0) = 1$.

- (d) (Mathematica) Use `DSolve` to solve the same IVP, and show the results are equal.

Solution: (a)

We seek the Laplace transform of $f(t) = t^5 e^{-4t} - 7 \sin(6t)$,

$$\mathcal{L}\{f(t)\}(s) = \mathcal{L}\{t^5 e^{-4t} - 7 \sin(6t)\}(s).$$

The Laplace transform is a linear operator, hence

$$\begin{aligned} &= \mathcal{L}\{t^5 e^{-4t}\}(s) + \mathcal{L}\{-7 \sin(6t)\}(s) \\ &= \mathcal{L}\{t^5 e^{-4t}\}(s) - 7\mathcal{L}\{\sin(6t)\}(s) \end{aligned}$$

We'll use the table to evaluate these,

$$\mathcal{L}\{e^{\alpha t} g(t)\}(s) = \mathcal{L}\{g(t)\}(s - \alpha) \quad \mathcal{L}\{t^n\}(s) = \frac{n!}{s^{n+1}}$$

Here, $\alpha = -4$, $g(t) = t^5$, and $n = 5$. Therefore

$$\mathcal{L}\{t^5 e^{-4t}\}(s) = \mathcal{L}\{t^5\}(s + 4) = \frac{5!}{(s + 4)^{s+1}} = \frac{120}{(s + 4)^6}$$

Now we'll evaluate the other using the table.

$$\mathcal{L}\{\sin(\alpha t)\}(s) = \frac{\alpha}{s^2 + \alpha^2}$$

Here, $\alpha = 6$, therefore,

$$\mathcal{L}\{\sin(6t)\}(s) = \frac{6}{s^2 + 6^2} = \frac{6}{s^2 + 36}$$

Hence, our transformation comes to

$$\begin{aligned} \mathcal{L}\{f(t)\}(s) &= \mathcal{L}\{t^5 e^{-4t}\}(s) - 7\mathcal{L}\{\sin(6t)\}(s) \\ &= \frac{120}{(s + 4)^6} - 7 \cdot \frac{6}{s^2 + 36} \\ &= \frac{120}{(s + 4)^6} - \frac{42}{s^2 + 36} \end{aligned}$$

Solution: (b)

We seek the Laplace transform of

$$f(t) = (t-1)^2 u(t-1) + \int_0^t f(\tau) \sin(t-\tau) d\tau,$$
$$\mathcal{L}\{f(t)\}(s) = \mathcal{L}\left\{(t-1)^2 u(t-1) + \int_0^t f(\tau) \sin(t-\tau) d\tau\right\}(s).$$

First, we'll use the linearity of the Laplace transform operator,

$$\mathcal{L}\{f(t)\}(s) = \mathcal{L}\{(t-1)^2 u(t-1)\}(s) + \mathcal{L}\left\{\int_0^t f(\tau) \sin(t-\tau) d\tau\right\}(s).$$

Second shifting theorem states

$$\mathcal{L}\{f(t-k)u(t-k)\}(s) = e^{-ks} \mathcal{L}\{f(t)\}(s).$$

In our case $k = 1$, and $f(t) = t^2$, hence

$$\mathcal{L}\{(t-1)^2 u(t-1)\}(s) = e^{-s} \mathcal{L}\{t^2\}(s) = e^{-s} \cdot \frac{2!}{s^{2+1}} = \frac{2e^{-s}}{s^3}$$

Convolution theorem states

$$\mathcal{L}\left\{\int_0^t f(\tau)g(t-\tau)d\tau\right\}(s) = \mathcal{L}\{f(t)\}(s) \cdot \mathcal{L}\{g(t)\}(s).$$

We have $f(\tau)$ and $g(t) = \sin(t)$. Hence,

$$\begin{aligned} \mathcal{L}\left\{\int_0^t f(\tau) \sin(t-\tau) d\tau\right\}(s) &= \mathcal{L}\{f(t)\}(s) \cdot \mathcal{L}\{\sin t\}(s) \\ &= \mathcal{L}\{f(t)\}(s) \cdot \frac{1}{s^2 + 1^2} \end{aligned}$$

Let $F(s) := \mathcal{L}\{f(t)\}(s)$. Hence, we have

$$\begin{aligned} \mathcal{L}\{f(t)(s)\} &= F(s) = \frac{2e^{-s}}{s^3} + F(s) \cdot \frac{1}{s^2 + 1} \\ \implies F(s) \left(1 - \frac{1}{s^2 + 1}\right) &= \frac{2e^{-s}}{s^3} \\ \therefore F(s) &= \frac{2e^{-s}}{s^3} \div \left(1 - \frac{1}{s^2 + 1}\right) \\ &= \frac{2e^{-s}}{s^3} \left(\frac{s^2 + 1}{s^2}\right) \end{aligned}$$

Therefore, an arbitrary function defined by the identify

$$f(t) = (t-1)^2 u(t-1) + \int_0^t f(\tau) \sin(t-\tau) d\tau$$

has Laplace transform

$$\mathcal{L}\{f(t)\}(s) = \frac{2e^{-s}(s^2 + 1)}{s^5}.$$

Solution: (c)(i)

```

1 In[1] := A = {{3, -4}, {-4, 3}};
2       y0 = {0, 1};
3       LapY = Inverse[s*IdentityMatrix[2] - A] . y0;
4       y = InverseLaplaceTransform[LapY, s, t]
5 Out[4] := {-(1/2) Exp[-t] (-1 + Exp[8 t]), 1/2 Exp[-t] (1 + Exp[8 t])}

```

First we set the matrix A to the coefficients, as they were given in the question, namely

$$\mathbf{Y}'(t) = A\mathbf{Y}(t) \iff \begin{pmatrix} y_1'(t) \\ y_2'(t) \end{pmatrix} = \begin{pmatrix} 3 & -4 \\ -4 & 3 \end{pmatrix} \begin{pmatrix} y_1(t) \\ y_2(t) \end{pmatrix}^T \implies A = \begin{pmatrix} 3 & -4 \\ -4 & 3 \end{pmatrix}.$$

Next we set a vector to represent the initial condition, \mathbf{y}_0 , by

$$\mathbf{Y}(0) = \begin{pmatrix} y_1(0) \\ y_2(0) \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

Applying the Laplace transform to

$$\mathbf{Y}'(t) = A\mathbf{Y}(t)$$

with $\mathbf{Y}(0) = \mathbf{y}_0$ yields

$$s\mathbf{Y}(s) - \mathbf{y}_0 = A\mathbf{Y}(s),$$

hence

$$(sI - A)\mathbf{Y}(s) = \mathbf{y}_0 \quad \text{and} \quad \mathbf{Y}(s) = (sI - A)^{-1}\mathbf{y}_0.$$

The inverse Laplace transform gets us our desired result!

Solution: (c)(ii)

```

1 In[1] := eqs = {y1'[t] == 3 y1[t] - 4 y2[t], y2'[t] == 3 y2[t] - 4 y1[t],
2       y1[0] == 0, y2[0] == 1};
3 In[2] := solDS = DSolve[eqs, {y1, y2}, t][[1]];
4 In[3] := solLap = {y1[t] -> -(1/2) Exp[-t] (-1 + Exp[8 t]),
5       y2[t] -> 1/2 Exp[-t] (1 + Exp[8 t])};
6 In[4] := ({y1[t], y2[t]} /. solDS) == ({y1[t], y2[t]} /. solLap)
7 Out[4] := True

```

We set the system of DEs, along with the initial values in the `eqs` variable. We then solve it numerically and store the first solution it found in `solDS`. Next we store the Laplace solution from the previous question in `solLap`. Finally, we compare the solutions, and find that they are equal.
